Instructions 1

Elevation of Privilege Instructions

Draw a diagram of the system you want to threat model before you deal the cards

Deal the deck to 3-6 players. Play starts with the 3 of Tampering. Play clockwise, and each player in turn follows in the suit if they have a card in the suit. If they don't have that suit, they can play another suit. The high card played takes the trick, with Elevation of Privilege taking precedence over the suit lead. Only Elevation of Privilege (EoP) or the lead suit can take a trick.

To play a card, read the card, announce your threat and record it. If the player can't link the threat to the system, play proceeds.

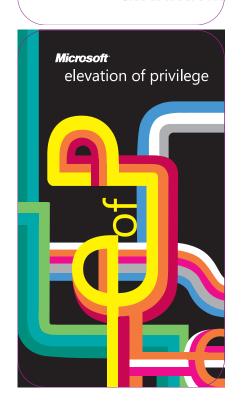

Take few minutes between hands to think about threats.

1 for a threat on your card, +1 for taking the trick

Instructions

Instructions

Elevation of Privilege Instructions

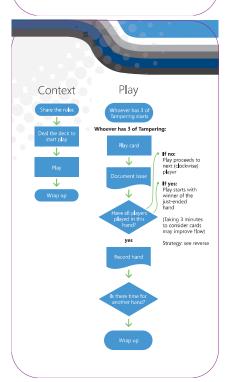

Threats should be articulated clearly, testable, and addressable. In the event that a threat leads to an argument, the threat should resolve by asking the question: "Would we take an actionable bug, feature request or design change for that?" If the answer is yes, it is a real threat. (This doesn't mean that threats outside of that aren't real, it's simply a way to focus discussion on actionable threats.) Questions that start with "There's a way" should be read as "There's a way...and here's how...
"while questions that start with "Your code" should be read
"The code we're collectively creating...and here's how."

The deck contains a number of special cards: trumps and open threats. EoP cards are trumps. They take the trick even if they are lower value than the suit that was led. The ace of each suit is an open threat card. When played, the player must identify a threat not listed on another card.

When all the cards have been played, whoever has the

Remember to have fun!

Instructions

Spoofing An attacker could squat on the random port or socket that the server normally uses

Instructions 2

Elevation of Privilege Variants

Optional/variants:

- You may pass cards after the third trick. This is helpful if you have cards that you can't tie to the system. Someone else may be able to.
- Double the number of points, and give one point for threats on other people's cards.
 Other players may "riff" on the threat and if they do, they get one point per additional threat.
- Limit riffing to no more than 60 seconds.
 Mark up the diagram with where the threat occurs.

Ouestions are listed on the threat cards to help

Thanks to Laurie Williams for inspiration.

Instructions

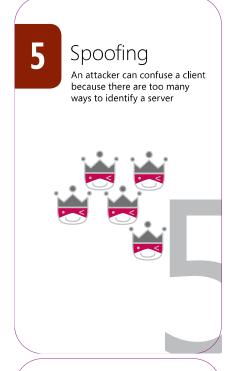

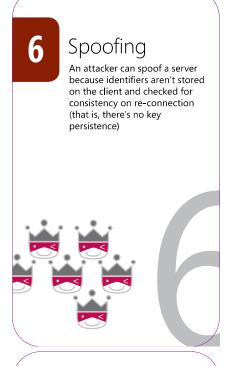

Spoofing

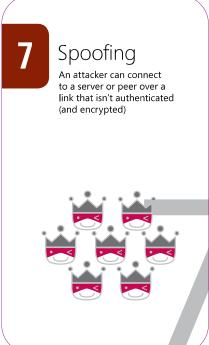

An attacker could try one credential after another and there's nothing to slow them down (online or offline)

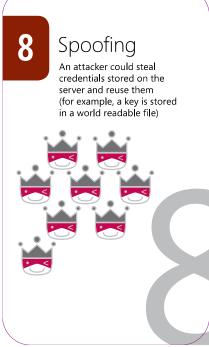

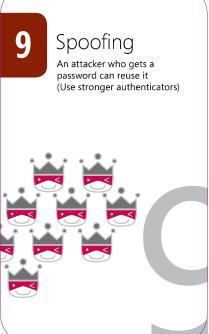

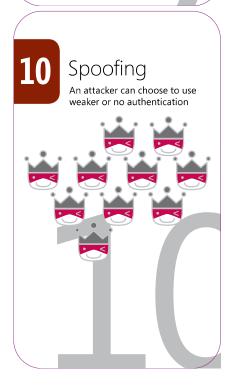

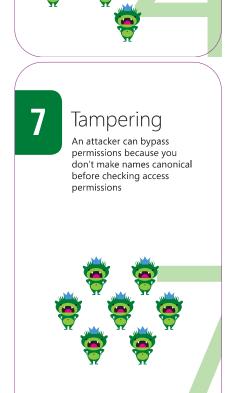

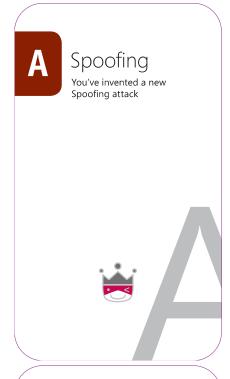

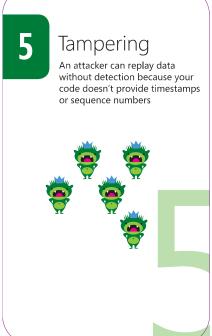

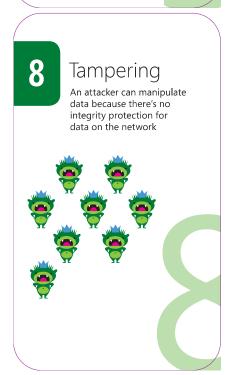

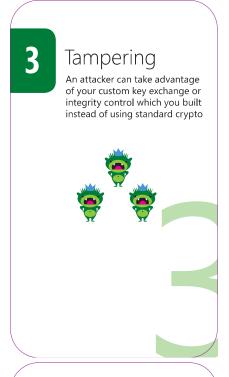

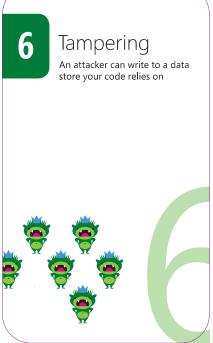

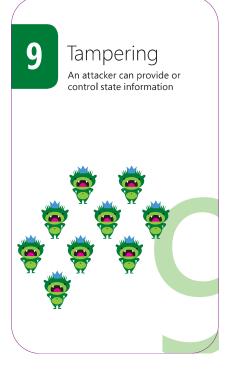

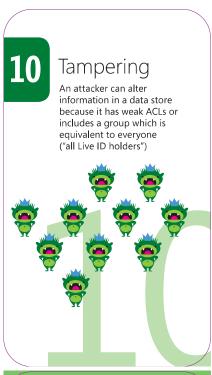

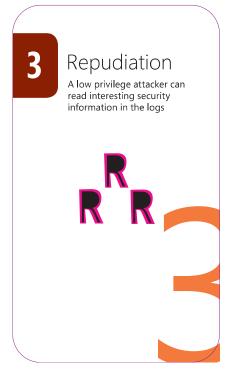

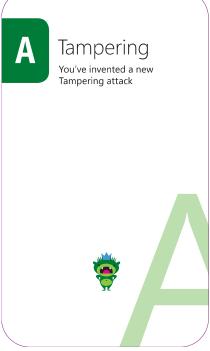

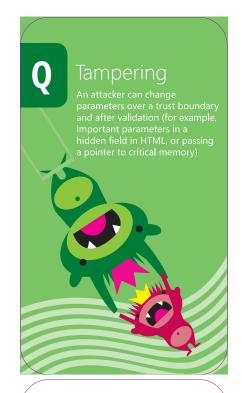

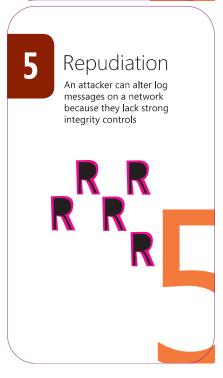

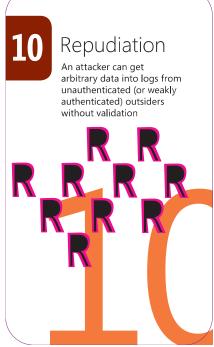

R R R

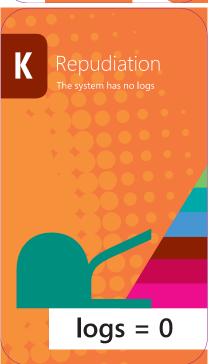

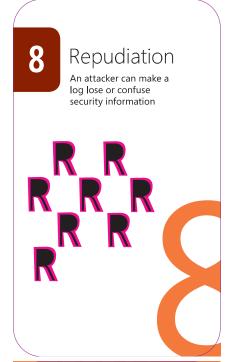

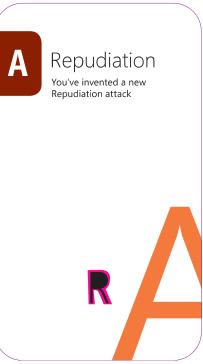

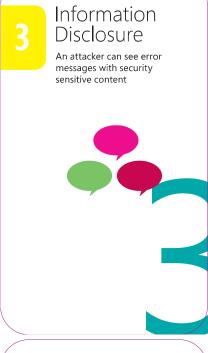

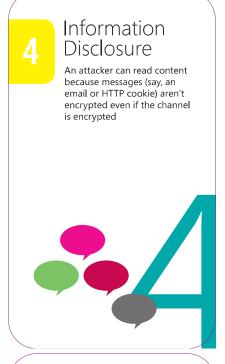

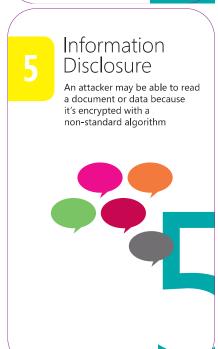

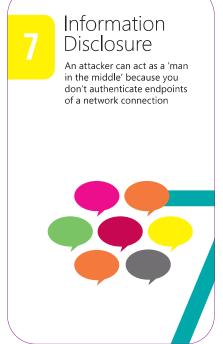

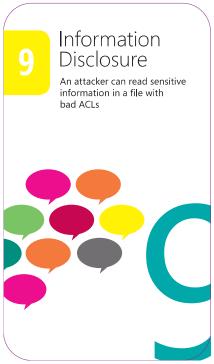

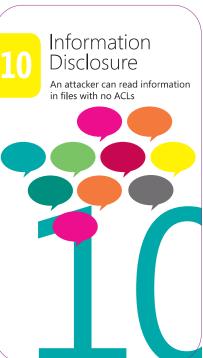

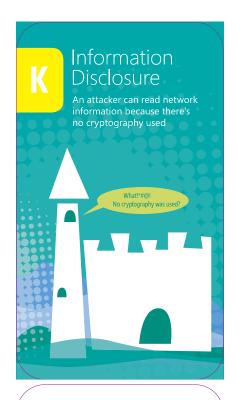

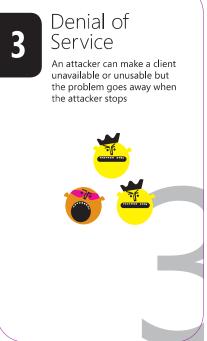

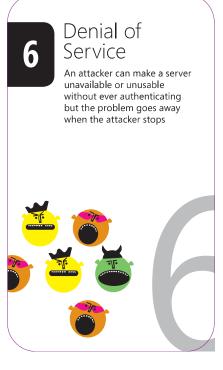

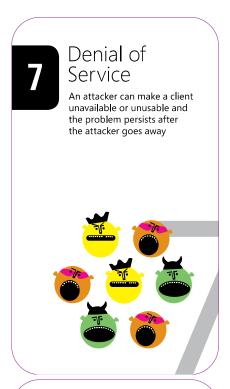

Denial of Service
An attacker can make your authentication system unusable or unavailable

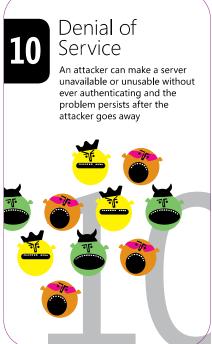

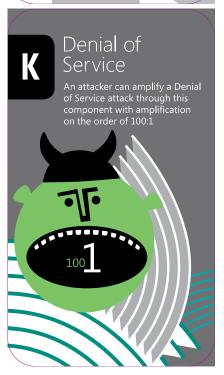

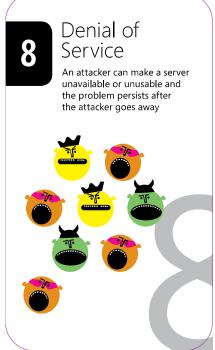

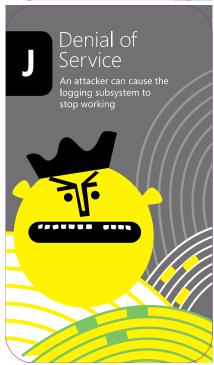

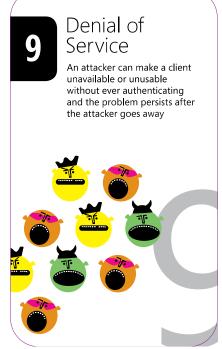

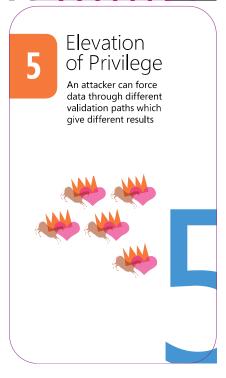

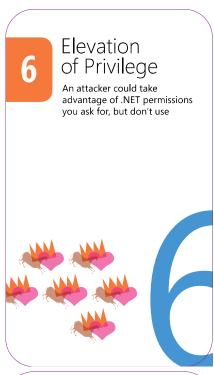

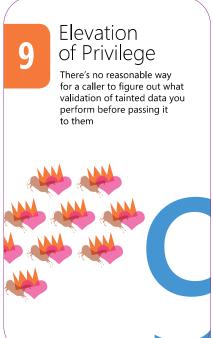

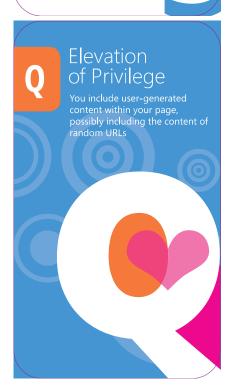

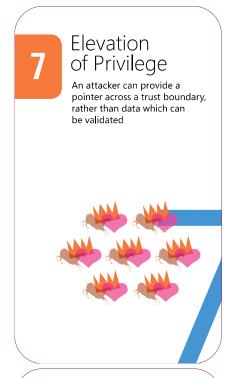

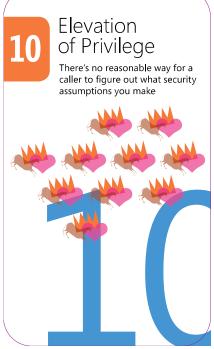

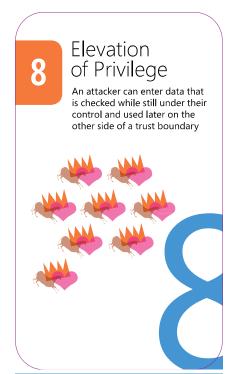

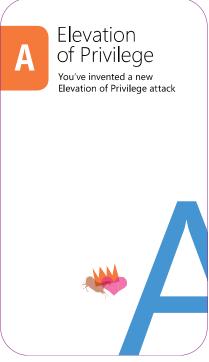

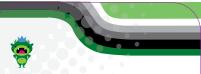

Spoofing

- 2. An attacker could squat on the random port or socket that the server normally uses
- 3. An attacker could try one credential after another and there's nothing to slow them down (online or offline)
- 4. An attacker can anonymously connect because we expect authentication to be done at a higher level
- 5. An attacker can confuse a client because there are too many ways to identify a server
- 6. An attacker can spoof a server because identifiers aren't stored on the client and checked for consistency on re-connection (that is, there's no key persistence)
- 7. An attacker can connect to a server or peer over a link that isn't authenticated (and encrypted)
- 8. An attacker could steal credentials stored on the server and reuse them (for example, a key is stored in a world readable file)
- 9. An attacker who gets a password can reuse it (Use stronger authenticators)
- 10. An attacker can choose to use weaker or no authentication

continued on back

Spoofing

Tampering cont.

- Q. An attacker can change parameters over a trust boundary and after validation (for example, important parameters in a hidden field in HTML, or passing a pointer to critical memory)
- K. An attacker can load code inside your process via an extension point
- A. You've invented a new Tampering attack

Tampering

Information Disclosure

- 2. An attacker can brute-force file encryption because there's no defense in place (example defense: password stretching)
- 3. An attacker can see error messages with securitysensitive content
- 4. An attacker can read content because messages (say, an email or HTTP cookie) aren't encrypted even if the channel is encrypted
- 5. An attacker may be able to read a document or data because it's encrypted with a non-standard algorithm
- 6. An attacker can read data because it's hidden or occluded (for undo or change tracking) and the user might forget that it's there
- 7. An attacker can act as a 'man in the middle' because you don't authenticate endpoints of a network connection
- An attacker can access information through a search indexer, logger, or other such mechanism
- 9. An attacker can read sensitive information in a file with bad ACLs
- 10. An attacker can read information in files with no ACLs continued on back

Information Disclosure

Spoofing cont.

- J. An attacker could steal credentials stored on the client and reuse them
- Q. An attacker could go after the way credentials are updated or recovered (account recovery doesn't require disclosing the old password)
- K. Your system ships with a default admin password, and doesn't force a change
- A. You've invented a new Spoofing attack

Spoofing

Repudiation

- 2. An attacker can pass data through the log to attack a log reader, and there's no documentation of what sorts of validation are done
- 3. A low privilege attacker can read interesting security information in the logs
- 4. An attacker can alter digital signatures because the digital signature system you're implementing is weak, or uses MACs where it should use a signature
- 5. An attacker can alter log messages on a network because they lack strong integrity controls
- 6. An attacker can create a log entry without a timestamp (or no log entry is timestamped)
- 7. An attacker can make the logs wrap around and lose
- 8. An attacker can make a log lose or confuse security information
- 9. An attacker can use a shared key to authenticate as different principals, confusing the information in the logs
- 10. An attacker can get arbitrary data into logs from unauthenticated (or weakly authenticated) outsiders without validation

continued on back

Repudiation

Information Disclosure cont.

- J. An attacker can discover the fixed key being used to encrypt
- Q. An attacker can read the entire channel because the channel (say, HTTP or SMTP) isn't encrypted
- K. An attacker can read network information because there's no cryptography used
- A. You've invented a new Information Disclosure attack

Information Disclosure

Tampering

- An attacker can take advantage of your custom key exchange or integrity control which you built instead of using standard crypto
- 4. Your code makes access control decisions all over the place, rather than with a security kernel
- 5. An attacker can replay data without detection because your code doesn't provide timestamps or sequence numbers
- 6. An attacker can write to a data store your code relies on
- 7. An attacker can bypass permissions because you don't make names canonical before checking access permissions
- 8. An attacker can manipulate data because there's no integrity protection for data on the network
- 9. An attacker can provide or control state information
- 10. An attacker can alter information in a data store because it has weak ACLs or includes a group which is equivalent to everyone ("all Live ID holders")
- J. An attacker can write to some resource because permissions are granted to the world or there are no ACLs continued on back

Tampering

Repudiation cont.

- 10. An attacker can get arbitrary data into logs from unauthenticated (or weakly authenticated) outsiders without validation
- J. An attacker can edit logs and there's no way to tell (perhaps because there's no heartbeat option for the logging system)
- Q. An attacker can say "I didn't do that," and you'd have no way to prove them wrong
- K. The system has no logs
- A. You've invented a new Repudiation attack

Repudiation

Denial of Service

- 2. An attacker can make your authentication system unusable or unavailable
- An attacker can make a client unavailable or unusable but the problem goes away when the attacker stops (client, authenticated, temporary)
- 4. An attacker can make a server unavailable or unusable but the problem goes away when the attacker stops (server, authenticated, temporary)
- 5. An attacker can make a client unavailable or unusable without ever authenticating but the problem goes away when the attacker stops (client, anonymous, temporary)
- 6. An attacker can make a server unavailable or unusable without ever authenticating but the problem goes away when the attacker stops (server, anonymous, temporary)
- 7. An attacker can make a client unavailable or unusable and the problem persists after the attacker goes away (client, authenticated, persistent)
- 8. An attacker can make a server unavailable or unusable and the problem persists after the attacker goes away (server, authenticated, persistent)
- An attacker can make a client unavailable or unusable without ever authenticating and the problem persists after the attacker goes away (client, anonymous, persistent)

continued on bac

Denial of Service

Denial of Service cont.

- 10. An attacker can make a server unavailable or unusable without ever authenticating and the problem persists after the attacker goes away (server, anonymous, persistent)
- J. An attacker can cause the logging subsystem to stop working
- Q. An attacker can amplify a Denial of Service attack through this component with amplification on the order of 10:1
- K. An attacker can amplify a Denial of Service attack through this component with amplification on the order of 100:1
- A. You've invented a new Denial of Service attack

Denial of Service

Threat Modeling

Elevation of Privilege is designed to be the easiest way to start looking at your design from a security perspective. It's one way to threat model, intended to be picked up and used by any development group. Because it uses the STRIDE threats, it gives you a framework for thinking, and specific actionable examples of those threats.

STRIDE stands for:

Spoofing Impersonating something or someone else.

Tampering Modifying data or code

Repudiation Claiming to have not performed an action Information Disclosure Exposing information to someone not authorized to see it

Denial of Service Deny or degrade service to users

Elevation of Privilege Gain capabilities without proper authorization

At www.microsoft.com/security/sdl/eop we have resources for you including videos, score sheets and tips and tricks for playing.

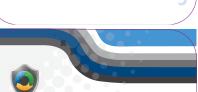

Abou

Elevation of Privilege (EoP)

- 5. An attacker can force data through different validation paths which give different results
- 6. An attacker could take advantage of .NET permissions you ask for, but don't use
- 7. An attacker can provide a pointer across a trust boundary, rather than data which can be validated
- 8. An attacker can enter data that is checked while still under their control and used later on the other side of a trust boundary
- 9. There's no reasonable way for a caller to figure out what validation of tainted data you perform before passing it to them
- 10. There's no reasonable way for a caller to figure out what security assumptions you make
- J. An attacker can reflect input back to a user, like cross site scripting
- Q. You include user-generated content within your page, possibly including the content of random URLs
- K. An attacker can inject a command that the system will run at a higher privilege level
- A. You've invented a new Elevation of Privilege attack

Elevation of Privilege

SDI

Elevation of Privilege is a fun and easy way to get started understanding the security of your systems by threat modeling. As you discover and correct design-level security problems, it's worth thinking about the other ways security issues can creep into your code. Microsoft has a large collection of free resources available to help you get started with the Security Development Lifecycle (SDL).
